

1 Lecture Plan

- Define pseudorandom generators.
- Construct a fixed-length private-key encryption scheme that has indistinguishable encryptions in the presence of an eavesdropper.
- Prove the security of the above scheme assuming the existence of a pseudorandom generator.

2 Pseudorandom Generators

- Pseudorandomness is a property of a *distribution* on strings.
- Some desirable properties of a pseudorandom generator:
 - Any bit of the output should be equal to 1 with probability close to $\frac{1}{2}$.
 - The parity of any subset of the output bits should be equal to 1 with probability close to $\frac{1}{2}$.
- A good pseudorandom generator should pass all efficient statistical tests, i.e. for any efficient statistical test or *distinguisher* D , the probability that D returns 1 given the output of the pseudorandom generator should be close to the probability that D returns 1 when given a uniform string of the same length.

Definition. Let l be a polynomial and let G be a deterministic polynomial-time algorithm such that for any n and $s \in \{0,1\}^n$, the result $G(s)$ is a string of length $l(n)$. We say that G is a **pseudorandom generator** if the following conditions hold:

1. **Expansion:** For every n it holds that $l(n) > n$.
2. **Pseudorandomness:** For any PPT algorithm D , there is a negligible function negl such that

$$|\Pr[D(G(s)) = 1] - \Pr[D(r) = 1]| \leq \text{negl}(n),$$

where the first probability is taken over uniform choice of $s \in \{0,1\}^n$ and the randomness of D , and the second probability is taken over uniform choice of $r \in \{0,1\}^{l(n)}$ and the randomness of D .

We call l the **expansion factor** of G .

- Example of a *non-pseudorandom generator*: Define $G : \{0,1\}^n \rightarrow \{0,1\}^{n+1}$ as $G(s) = s \parallel (\oplus_{i=1}^n s_i)$.
- What happens if remove the restriction that D is polynomial time?
- There is no known way to prove the unconditional existence of pseudorandom generators. We will see some constructions of stream ciphers which we hope are pseudorandom generators.

3 A Secure Fixed-Length Encryption Scheme

- Let G be a pseudorandom generator with expansion factor l . Define a private-key encryption scheme for messages of length l as follows:
 - **Gen**: On input 1^n , choose k uniformly from $\{0,1\}^n$.
 - **Enc**: Given $k \in \{0,1\}^n$ and message $m \in \{0,1\}^{l(n)}$, output the ciphertext

$$c := G(k) \oplus m.$$

- **Dec**: Given $k \in \{0,1\}^n$ and ciphertext $c \in \{0,1\}^{l(n)}$, output the message

$$m := G(k) \oplus c.$$

Theorem. *If G is a pseudorandom generator, then the above construction is a fixed-length encryption scheme that has indistinguishable encryptions in the presence of an eavesdropper, i.e. for any PPT adversary \mathcal{A} there is a negligible function negl such that*

$$\Pr [\text{PrivK}_{\mathcal{A}, \Pi}^{\text{eav}}(n) = 1] \leq \frac{1}{2} + \text{negl}(n).$$

Proof. Note that if a one-time pad is used instead of the pseudorandom generator $G(k)$, the system is EAV-secure. The key idea is that if a PPT adversary \mathcal{A} can distinguish between the encryptions of m_0 and m_1 , then it can distinguish between $G(k)$ and a uniformly random bitstring.

Distinguisher D : D is given a string $w \in \{0,1\}^{l(n)}$ (assume n can be determined from $l(n)$)

1. Run $\mathcal{A}(1^n)$ to obtain a pair of messages $m_0, m_1 \in \{0,1\}^{l(n)}$.
2. Choose a uniform bit $b \in \{0,1\}$. Set $c := w \oplus m_b$.
3. Give c to \mathcal{A} and get b' . If $b = b'$ output 1 and output 0 otherwise.

If \mathcal{A} succeeds, D decides that w is a pseudorandom string and if \mathcal{A} fails D decides w is a random string.

Rest of proof done in class. □
